HealthConnect Rwanda Week 7
Project Summary

Week 7 focused on testing the supplied Week 6 MySQL analysis, KPI script, Power BI dashboard, quality findings, business report and presentation. The objective was to validate important totals, preserve records across joins, clarify metric definitions and improve the reliability of recommendations before Week 8.

The independent source review executed 41 analysis SELECT statements and 60 KPI SELECT statements in Python and SQLite with documented MySQL compatibility mappings. Thirteen refinement queries were then executed, and all 14 targeted retests passed. Static dashboard inspection identified 13 pages, including six core analytics pages, and 19 tables in the model diagram. Chart quality and displayed KPI acceptability were accepted from the supplied reviewer confirmation; native MySQL and Power BI runtime were not executed.

The source controls reconcile to 20,000 patients, 5,000 available appointments, 1,250 staff, 350 doctors and average feedback of 2.99. Billed value is 9,309,401,961, collected payments are 8,389,454,556 and outstanding balance is 919,947,405. The executive reported-revenue card uses Revenue Summary, whose total is 1,132,677,500, rather than collected payments.

Testing exposed join-grain and coverage risks. A controlled bed-detail join multiplied department appointment counts to 50,000; a unique department lookup restored 5,000. Payment-led queries retain the full collection total, including 7,694,903,236 without appointment attribution. Laboratory tests now retain all 5,000 records. Other refinements provide numeric rating frequencies; distinct equipment counts and clear workforce-ratio definitions. Week 7 also corrects the quality document referral count to 4,708 data records.

Important decisions were to preserve the original files, retain Unknown groups, separate appointment and clinical-event workloads, and distinguish reported revenue from collections and claims. These findings support reliable analytical handover. The remaining challenges are incomplete appointment parents, conflicting master assignments, absent transaction and activity dates, and no attendance/no-show target. Stronger profitability, utilization and attendance conclusions require additional authoritative data.

Cross-track collaboration was not completed, so no shared test, exchanged output or joint improvement is claimed. GitHub publication has not yet been undertaken. Before Week 8, apply the refined SQL in the native project environment, retain the evidence scope, address key and date dependencies, and complete the required publication and submission actions.
